A Convenient Synthesis of C₅(CD₃)₅H. Synthesis and Characterisation of Fe{η⁵-C₅(CD₃)₅}₂

Dermot O'Hare, Juan Manriquez, and Joel S. Miller*

Central Research and Development Department, E. I. du Pont de Nemours and Co., Inc., Experimental Station E328, Wilmington, Delaware 19898, U.S.A.

The large scale synthesis of deuterio(pentamethylcyclopentadiene), C₅(CD₃)₅H ([2H₃0]Cp*H), and subsequent synthesis of [2H₃0][Fe(1'-Cp*)₂] is described, together with i.r., Raman, and solid state ²H n.m.r. spectroscopic characterisation.

Since the discovery and structural characterization of ferrocene, at least one cyclopentadienyl, Cp, derivative of every main group, transition, and f-block metal has been reported.¹ Catalytic H/D exchange of the C–H bonds of cyclopentadiene² has been known for some time and has been beneficially used to synthesize labelled metallo-cyclopentadienyl complexes for use in n.m.r., e.p.r., matrix isolation, kinetic, and mechanistic studies. These experiments have proven vital to the understanding of the structure and bonding in organometallic complexes as well as providing definitive evidence for the mechanism of many fundamental reactions involving organometallic compounds. Extensive study of metallo-permethycyclopentadienyl compounds was not practical until the development of efficient synthetic routes to pentamethylcyclopentadiene, Cp*H.³ Subsequently, many papers demonstrating the dramatic differences between the structure and chemistry of Cp and Cp* have appeared.⁴

Although intramolecular H/D exchange of the methyl hydrogens of the Cp* ligands in complexes such as [(η-Cp*)₂MH; M = Hf,⁵ Sc⁶] have been reported, these are stoichiometric reactions and decomplexation of [²H₃0]Cp* is problematic. Herein we report the bulk catalytic synthesis of C₅(CD₃)₅H, and the characterisation of [²H₃0][Fe(η-Cp*)₂].

At elevated temperature under a D₂ atmosphere, (η-Cp*)₂ScD (readily prepared in a three step synthesis from anhydrous ScCl₃)⁷ catalyses multiple H/D exchanges of
C₅(CH₃)₅H (1a) with C₆D₆ (equation 1). † ¹H N.m.r. spectroscopy at 145 °C shows that the rate of H/D exchange of all the methyl hydrogens is 10 turnovers/day. Deuteration incorporation occurs in a one-at-a-time manner. This is in contrast to H/D exchange catalysts based on [PtCl₄]²⁻ (ref. 7) and zirconium alkoxides,⁸ which have been reported to effect multiple deuterations per interaction with the catalyst. We observe that the allylic hydrogen exchange is much slower; only after 4—5 weeks can deuterium incorporation into this position be detected by n.m.r. or mass spectroscopy.

The large scale synthesis of C₅(CD₃)₅H (1b)‡ can be achieved using moderate amounts of the (η-Cp*)₂ScD catalyst. The typical isotopic purity as calculated from the intensity distribution of isotopomers is typically 95—96% after 4—5 week reaction times. Enriched (1b) can be isolated from the solvent in 90% yield via fractional distillation. In addition, the catalyst can be recycled for use in further exchange reactions. The unexchanged allylic hydrogen can be conveniently removed with LiBu₄ giving lithium perdeuterio-

pentamethylcyclopentadienide. The Li⁺[²H₅][Cp⁺]— can now be used as the primary synthon for labelled transition metal Cp⁺ complexes, e.g. [²H₅][Fe(η-Cp⁺)] (2b) and [²H₅][Fe(η-Cp⁺)₂]⁺[BF₄]⁻ (3b), which were prepared and characterised.

The vibrational spectroscopy of metallocyclopentadienyls has received much attention. The i.r., Figure 1, and Raman spectra, Figure 2, of (2a) and (2b), although unassigned, exhibit C−H stretching vibrations at ca. 3000 cm⁻¹ which are shifted upon deuteration by (2)¹ /² to ca. 2120 cm⁻¹. In addition the Raman spectrum, Figure 2, shows an absorption at ca. 640 cm⁻¹ which is unshifted upon deuteration and may be assigned to a symmetrical ring mode.

²H Solid state n.m.r. spectroscopy of organometallic inclusion complexes, intercalation reactions, and charge transfer salts relies on the synthesis of suitable labelled compounds. For metallocenes, it offers the opportunity of investigating the dynamics of both η-Cp⁺ ring rotation and methyl rotation in the solid state. The room temperature solid state static ²H n.m.r. spectrum of (2b) shows a classical axial powder spectrum with the dominant doublet feature separated by 18.3 kHz. A simulation of the powder spectrum using a model where we have both rapid methyl rotation and η-Cp⁺ rotation (we have assumed the rigid limit quadrupole constant e²qQ/h = 165 kHz) gives a doublet separation of 21 kHz which is in good agreement with the observed spectrum.

It is clear that the availability of deuterium labelled Cp⁺H

---

† 1 atm D₂, (η-Cp⁺)₂ScD (1 g, 0.1 equiv.), 150 °C, Cp⁺H (10 g), C₆D₆ (150 ml).

‡ Selected data for (1b): ³H(¹H) n.m.r. (C₅H₅) δ 1.65 (s, 2Me), 1.59 (s, 2Me), 0.85 (s, Mc); mass spectrum, m/z 151 (100%, C₅D₅,H). For (2d): ³H(¹H) n.m.r. (C₅H₅) δ 1.95 (s); m/z 356, P⁺. For (3d): ³H(¹H) n.m.r. (MeCN) δ −34.8 (s); m/z 356, P⁺.

---

Figure 1. The infrared spectra of (a) (2a) and (b) (2b) in KBr.
(1b) and in turn labelled metallocyclopentadienyl complexes will assist in the assignment of vibrational and magnetic resonance spectra in addition to elucidating mechanistic pathways.

Note added in proof: (2b) can also be prepared in greater than 99.9% isotopic purity via a stoicheiometric ligand exchange reaction (1). Typically, Fe(acac)$_2$ (4 g) dissolved in 

\[
[\text{H}_3\text{O}][(\eta^5-\text{Cp}^\*)_2\text{ScCl}] + 1.5 \text{Fe(acac)}_2_{\text{toluene}} + 0.5 \text{FeCl}_2 \xrightarrow{\text{reflux}} (2b) + \text{Sc(acac)}_3
\]

acac = pentane-2,4-dionate
toluene (50 ml) was added to a solution of [\text{H}_3\text{O}][(\eta^5-\text{Cp}^\*)_2\text{ScCl}] prepared from 4 g of [(\eta^5-\text{Cp}^\*)_2\text{ScCl}]$^\text{6}$ The reaction mixture was heated under reflux for 12 h, the solvent was removed under reduced pressure, and the residue was extracted with pentane. After drying the extract and sublimation, 2.5 g (62%) of (2b) was collected. The $^1$H impurity was determined by mass spectral analysis to be <0.03%.

We thank R. Farlee (n.m.r.), E. Mathews (i.r.), F. Kitson (g.c.-m.s.), B. Chase (Raman), and D. Wipf (technical assistance). We are also indebted to J. E. Bercaw and M. E. Thompson for helpful discussions. D. O. H. is currently on leave from the Inorganic Chemistry Laboratory, University of Oxford, Oxford OX1 3QR, U.K.
